10. Exploring the consequences of fossil fuel CO_2 emissions

10.0 For the next experiment(s) you can chuck CO_2 into the atmosphere, just for the hell of it. As much as you want! Apparently, humans are actually doing this now. Imagine that!

The *user-config* for *c*GENIE, `exp8_co2emissions` is provided and configured with climate being responsive to CO_2 (i.e., it takes account of CO_2-climate feedbacks):

```
# set CO2-climate feedback
ea_36=y
```

as well as a rate of calcification in the surface ocean that is responsive to *p*H (i.e., it takes into account CO_2-calcification feedbacks, which will additionally interact with climate – see *Ridgwell et al.* [2007b]). Anything could happen!!!

In the *user-config*, a release of CO_2 to the atmosphere is prescribed, which by default is set for 1000 PgC over an interval of a single year. (Releasing CO_2 just over a single year is obviously rather unrealistic, but represents a useful idealized experiment for assessing the time-scale(s) of fossil fuel CO_2 uptake by the ocean.) Additional results output has also been prescribed:

```
bg_ctrl_data_save_slice_ocnatm=.true.
bg_ctrl_data_save_slice_fairsea=.true.
bg_ctrl_data_save_slice_carb=.true.
bg_ctrl_data_save_slice_ocnsed=.true.
bg_ctrl_data_save_sig_carb_sur=.true.
bg_ctrl_data_save_slice_misc=.true.
bg_ctrl_data_save_derived=.true.
```

Because the *base-config* (`cgenie_eb_go_gs_ac_bg.worjh2.BASE`) has changed yet again! (carbon cycle tracers have now been added), you will first need to do a `make cleanall`.

10.1 Run the experiment for e.g., 20 (or more) years, starting from the re-start used previously, i.e.,:

```
$ ./runcgenie.sh cgenie_eb_go_gs_ac_bg.worjh2.BASE LABS
 exp8_CO2emissions 20 exp0_modern16_SPINUP
```

and view the run-time output, particularly atmospheric CO_2 (which decays away after the first year as fossil fuel CO_2 is progressively taken up by the ocean), ocean surface temperature (SST), sea-ice extent, and Atlantic Meridional Overturning ('`AMO`') strength. Viewing the time-series results file `biogem_series_fexport_CaCO3.res` will show how global carbonate production responds to the ensuing ocean acidification, which itself is recorded in the file: `biogem_series_misc_surpH.res`.

In the 3-D netCDF time-slice file, ocean pH is a particularly relevant field to consider together with calcite and aragonite saturation – note that ocean surface waters in which aragonite becomes under-saturated ($\Omega < 1.0$) is regarded as a critical threshold for organisms making aragonite shells and skeletons and spells TROUBLE for some poor calcifying marine organism somewhere.

In the 2-D netCDF time-slice file you are given water column integrals of dissolved things (e.g., DIC - `ocn_DIC_int`) (see: *Sabine et al.* [2004]; *Science* **305**). Also saved is the benthic (bottom water) conditions of ocean properties and carbonate chemistry – relevant for assessing the changes in environmental conditions affecting e.g. cold-water (deep-dwelling) corals.

Also try creating difference maps in Panoply to assess the geographical characteristics of ocean acidification impacts. Ideally, one would run a parallel experiment, identical except for zero CO_2 release being specified, to act as a 'control' for the calculation of the differences. A difference map for the water-column integral of DIC (2D netCDF file), for instance, reveals where fossil fuel CO_2 is preferentially taken up by the ocean.

10.2 You can easily modify the experimental design to release more/less CO_2 as you did for the red dye tracer. In the *user-config* file, the lines:

```
bg_par_atm_force_scale_val_3=1000.0
bg_par_atm_force_scale_val_4=-27.0
```

scale the CO_2 flux and its $\delta^{13}C$ isotopic signature, respectively. The scaling values are given to you for a CO_2 release of 1000 PgC yr^{-1} (current emissions are about 8 PgC yr^{-1}) at -27‰ (typical of fossil fuel carbon). Altering the value assigned to `bg_par_atm_force_scale_val_3` in the *user-config* file gives immediate control over emissions rate.

You can also adjust the emissions to have a time-varying rate by editing the file:

`biogem_force_flux_atm_pCO2_sig.dat`

which can be found in the directory:

`cgenie/genie_forcings/pyyyyz_FpCO2_Fp13CO2`

The format of this file is:

```
-START-OF-DATA-
     0.0  8.3333e+013
     1.0  8.3333e+013
     1.0  0.0
999999.9  0.0
-END-OF-DATA-
```

and defines a total emission of 1000 PgC (8.333×10^{16} mol CO_2) over the first 1 year of the model experiment. (Year 999999.9 has no special meaning and is simply just way in the future …)

Pause … and note briefly how the final CO_2 flux is arrived at. GENIE calculates it by multiplying the value in the *forcing* file (`8.3333e+013`) by a modifying parameter in the *user config* file (`1000.0`). The total flux is hence: $8.333\times10^{13} \times 1000 = 8.333\times10^{16}$ mol CO_2.

Equally, we could have had `1.0` in the *forcing* file and `8.3333e+016` as the value of `bg_par_atm_force_scale_val_3`. OR, the other way around.

The way you have been given is simply for my own convenience in 'hiding' the units conversion in the *forcing* file and allowing me to simply enter a value in PgC yr^{-1} in the *user config* file. It is entirely up to you if you prefer to do things differently.

10.3 Between the start and end 'tags', the data is in 2 columns: the first contains a series of tie-points for defining the timing of changes in emissions, and the 2nd contains the flux information (units of mol yr^{-1}). At each time-step of the model the CO_2 flux is interpolated between these time points.

The purpose of:

```
     0.0  8.3333e+013
     1.0  8.3333e+013
     1.0  0.0
```

is thus to effect a sharp turn-off of the flux at the end of first year. To extend the period of emissions – for example:

```
     0.0  8.3333e+013
    10.0  8.3333e+013
    10.0  0.0
```

would give you 1000 PgC yr^{-1} over 10 years. In contrast;

```
     0.0  0.0
    10.0  8.3333e+013
```

would result in a linear ramp, zero at the start of year `0.0` to `8.3333e+016` mol yr^{-1} at year 10.0 (a total CO_2 emission of $1000\times10\times0.5 = 5000$ PgC over 10 years).

It is also possible to provide a simple scaling of the duration of the pulse by adding the lines:

```
bg_par_atm_force_scale_time_3=10.0
bg_par_atm_force_scale_time_4=10.0
```

which would scale the duration of the pulse (of CO_2 and its isotopic signature) by a factor to 10, i.e., to 10 years. (Remember, that without changing the default emissions <u>rate</u>, you will end up with 10,000 PgC total CO_2 emitted … !)

10.4 By editing (and saving) the flux (and/or timing information) you can exert fine control on the CO_2 emissions trajectory and total fossil fuel burn. For instance, the IPCC 'SRES' scenarios of possible future CO_2 emissions can be reconstructed and their implications tested in GENIE. Play with different CO_2 releases and note their impact on climate and ocean biogeochemistry. Much more realistic and appropriate to our current global experimenting is a lower rate (order of 10 or 20 PgC yr^{-1}) released over a longer interval.
